Visualizing the Accessibility by Air (AbA): Examples for Urban Destinations in Europe

A major competitive advantage of a destination is its accessibility by air. Cities and airports are advised to carefully monitor the airlines' flight schedules that will be reflected in the passengers' perceptions of reachability. An AbA Index is constructed for 219 European destinations and 15 departure airports. The Index is based on the travelers' combined flight and waiting time. The information hidden in the 219-by-15 matrix is subjected to data compression and visualization. Self-Organizing Maps are used for condensing the accessibility information into a two-dimensional array that portrays the density of flight connections offered by a particular airport.

Keywords: Accessibility, airport, urban destination, air transport

Markus M. Felber, doctoral candidate in business administration at the Institute for Tourism and Leisure Studies (tourism.wu-wien.ac.at), Vienna University of Economics and Business Administration (WU Wien); studies of Mathematical Computer Science at the Vienna University of Technology (TU Wien). Research interests: measuring customer satisfaction, market segmentation, cluster analysis, leisure and tourism.

Josef A. Mazanec, full professor of business administration; head of the Institute for Tourism and Leisure Studies (tourism.wu-wien.ac.at) of the Vienna University of Economics and Business Administration (WU Wien) since 1981. Visiting scholar, Alfred P. Sloan School of Management, MIT, 1992. Vice-Rector for Research of the WU Wien 1997-2002; Speaker of the Joint Research Program on *Adaptive Information Systems and Modeling in Economics and Management Science* 1997-2001. Research interests: consumer behavior, strategic marketing, decision-support systems, management science applications in hospitality, leisure and tourism.

Jürgen Wöckl, post-doctoral researcher; member of staff in the research program for adaptive modeling and computer simulation at the Vienna University of Economics and Business Administration (WU Wien) since 2001. Doctoral degree in Applied Mathematics from the Vienna University of Technology (TU Wien), 2003; graduate (Master) from a joint study program of physics and economics of the TU Wien, 2000. Research interests: adaptive modeling and simulation, artificial consumer market models, multidimensional data analysis and statistical learning, inferred causation and MCMC methods.

Operationalizing the Index of Accessibility by Air

The index for measuring the Accessibility by Air was developed by the Institute for Transport and Logistics of the Vienna University of Economics and Business Administration. Other examples of indices measuring accessibility were introduced by Bökemann and Kramer (1999), Allen et al. (1993), Gutiérrez (2001), Brilon and Reichardt (1994), Rietveld and Bruinsma (1998), Lutter et al. (1993) and Gosling (1999). The underlying project (see Kummer and Medenbach, 2004) aimed at determining the economic importance of air transport for the Greater Vienna region. The index is defined by

$$A_i = \frac{1}{T_{ij}}$$

where the total duration of a trip from departure airport i to the destination j

$$T_{ij} = TT + CT + WTD$$

with

TT : Travel Time, i.e. the actual flight duration according to the schedule. An expected amount of delay time based on the average of all flights is included. The WTC = Waiting Time on Connecting Flights is incorporated into the TT .

CT : Check-In/Check-Out Time, i.e. the time consumed before take-off and after disembarking including all security controls.

WTD : Waiting Time on Departure, depends on the number of flights within a time period (7 a.m. – 7 p.m.) according to

$$WTD = \frac{720\text{Minutes}}{\text{Number of flights} + 1}$$

At first glance the index seems to reflect the intuitive concept one may bear in mind when judging the reachability of a city from the air passenger's point of view. But there are caveats. A flight offered in addition to what is already considered in the index may deteriorate the index value. This happens if the increase in the average Travel Time excels the decrease of the Waiting Time on Departure. Therefore, it is recommended to restrict the choice of connections to direct flights.

So far, the type of aircraft is not considered. The seating capacity might be incorporated by applying a weighting factor. Finally, the time span for the calculation of the Waiting Time on Departure was deliberately fixed at 7:00 a.m. to 7:00 p.m.; the flights offered during night time do not enter the comparison.

Visualizing the Accessibility by Air from a particular origin

The Accessibility Index shown in this example covers 219 destinations and 15 departure airports. The bulk of information hidden in a table of 219 rows and 15 columns needs an efficient tool for data compression. Self-Organizing Maps (Kohonen 1982, 1989, 2001; Kohonen et al. 2000) are used for condensing the accessibility information into a two-dimensional format. The maps are not a geographical representation. Rather they mimic the topological structure of the destinations in the 15-dimensional accessibility space in just two

dimensions.¹ In a first step the destinations are classified into ‘prototypes’ i.e. airports with a similar profile of accessibility values for the 15 departure airports selected earlier. In this example the ‘accessibility map’ consists of an array of six-by-six cells. Each cell or map position contains the destinations of similar accessibility (cf. Exhibit 1 and Table A1 in the Appendix). The data reduction, therefore, replaces the 219 destinations by 36 accessibility ‘classes’. According to the topology-preserving property of the map the neighborhood structure of the destinations also conveys meaningful information: Destination prototypes lying adjacent to each other are more similar in terms of their accessibility profile than destination cells farther apart.

From the airport or airline management point of view the major question addresses the performance of a departure airport in serving the 219 European destinations. To improve the quality of visualization the ‘coverage’ of each departure airport/city is indicated by shaded colors. A darker shade of grey denotes a higher index of accessibility and the destinations collected in this map position are more easily accessible from the departure airport under study. Table A2 in the Appendix describes the degree of accessibility of 36 classes of destinations from each departure airport represented by a column (‘outbound reachability’). The map conveys an instantaneous impression of an important facet of the relative competitive strength of a departure airport viz. its coverage of destination. More cells of darker shading point to stronger competitiveness. In the visualization actually two elements of the structure of competition among the airports become apparent: the width and the intensity of the coverage of the destinations, and the overlap or exclusiveness of the destinations served in comparison with the competitors.

The sample maps in the Exhibits 2 to 5 for Vienna, Frankfurt, Paris and Salzburg also demonstrate well-known phenomena such as

¹ For a more rigorous explanation of the Kohonen Map with an empirical application to measuring and comparing the company images of luxury hotels see Mazanec (1995).

- the competitive advantage in the home markets
- the amount of specialization
- the dense coverage of East and South-East European destinations ex Vienna
- destinations with a frequent or a rare accessibility profile
- the difference in magnitude between the global and the regional players in this market.

It is worth noting that the results are always relative to the departure airports chosen. The managers may decide on the selection of airports with respect to competitive threat. A more refined visualization may also portray the importance in terms of passenger turnaround by the size of each cell. The visualization procedure may also incorporate a dynamic aspect and contribute to the benchmarking and monitoring toolkit of the airlines and airports.

Example of a visualization applet: For live illustration of a different format of the accessibility visualization a Java-based tool is provided. The program is based on a platform independent Java applet which allows for interactive usage on the internet (try http://tourism.wu-wien.ac.at/e_index/VisSom.jar.html). Java applets are a client-side technology where an appropriate Java installation on the user's computer for internet access is needed and the Java support of the browser has to be enabled. The applet was tested under Sun's J2SE 1.4.2 and J2SE 5.0.

The visualization is subdivided into two layers to provide a complete description of the destination nodes in the SOM. The nodes are represented by bubbles (see the screenshot in Exhibit 6). On the first layer (node layer) of the map only the name of one popular destination among the cities represented by each node is printed next to the bubble. (See Table A1 in the Appendix for the full list of destinations and their respective SOM positions.) The area of a bubble is proportional to the mean accessibility value of the destinations collected in this node given a particular departure airport. With the airport selector on the node layer the user chooses one of the 15 departure airports i.e. one of the columns in the Table A2 of the Appendix (cf.

Paris in Exhibit 6). All bubbles are click-able to retrieve the destination names. The mouse click opens the second layer and a list of the destinations assigned to the selected node is displayed showing their names and their accessibility index values (Exhibit 7). On this second layer (list layer) the airports may be marked and added to a text field for copying and subsequent processing. Placing the mouse pointer on the node layer inside a bubble makes a tool tip window pop up showing a preview of the airports assigned to this bubble (see Bologna etc. in Exhibit 6). The setup menu provides functions such as altering the text size, the bubble and text overlapping, or the factor of proportionality between the accessibility values of the nodes and the bubble size.

In this visualization the destination coverage – a major component of the competitive strength of a departure airport -- is expressed by the number of large-sized bubbles.
